

## Rational Quadratic Zeros

In this lesson, you will extend the code from **Integer Quadratic Zeros**. If you didn't complete the activity, complete that activity first or obtain the base code from your teacher.

In this lesson, you will create a game that lets you practice finding x-intercepts for equations in the form  $y = ax^2 + bx + c$ . These solutions will have one rational and one integer solution.

In the challenge, you will apply what you have learned to create a third game. This game will let you practice finding x-intercepts for equations in the form  $y = ax^2 + bx + c$  where both x-intercepts are rational numbers.

### Objectives:

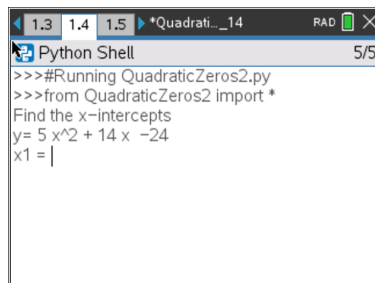

#### Programming Objectives:

- Use the input function and a variable to collect and store data from a user
- Use the randint() function to generate random integers.
- Use a while loop to repeat code
- Use if..elif..else statements to make decisions.

#### Math Objectives:

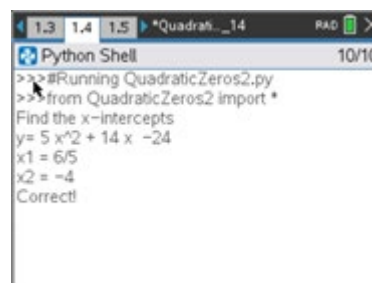

- Explore how x-intercepts are related to factored quadratic equations
- Explore how to factor equation in standard form
- Factor quadratic equations with rational solutions

In this lesson, you will create a game that lets you practice finding x-intercepts for equations in the form  $y = ax^2 + bx + c$ . These solutions will have one rational and one integer solution.

```

>>>#Running QuadraticZeros2.py
>>>from QuadraticZeros2 import *
Find the x-intercepts
y= 5 x^2 + 14 x -24
x1 = |
  
```

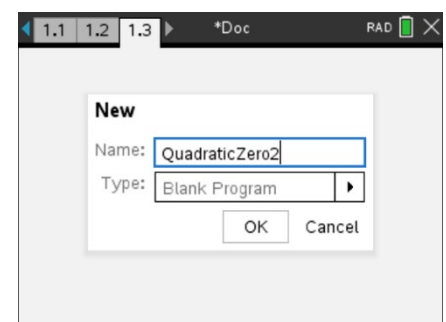

```

>>>#Running QuadraticZeros2.py
>>>from QuadraticZeros2 import *
Find the x-intercepts
y= 5 x^2 + 14 x -24
x1 = 6/5
x2 = -4
Correct!
  
```

1. Insert a third page into the Integer Quadratic Zeros document.

Add a python page.

Name the project **QuadraticZero2**

2. This project will be a modification of QuadraticZero.

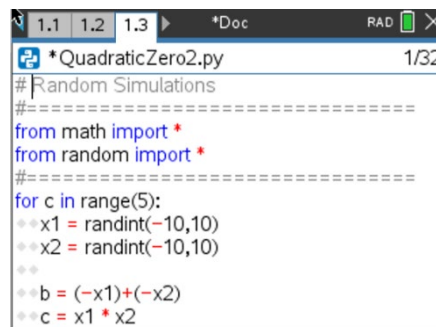

Go back to page 1.1.

Select all the code (ctrl -> a)

Copy the code (ctrl -> c)

Go to page 1.3, QuadraticZero2

Paste the code (ctrl -> v)

```
*QuadraticZero2.py 1/32
# Random Simulations
#=====
from math import *
from random import *
#=====
for c in range(5):
  x1 = randint(-10,10)
  x2 = randint(-10,10)
  b = (-x1)+(-x2)
  c = x1 * x2
```

3. The factored equations in this problem will be of the type:

$$y = (m \cdot x - x_1)(x - x_2)$$

In the first project, the line

$$x_2 = \text{randint}(-10,10)$$

creates and stores random integer value from -10 to 10 in the variable x2

Similarly, we will let m be an integer value from two to seven.

Add a line of code after the  $x_2 = \text{randint}(-10,10)$  to generate and store the value of m.

4. How does the addition of the coefficient m change the values of b and c in the code?

Use distribution to solve and rewrite the equation in standard form.

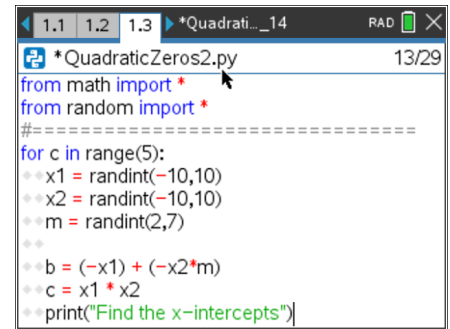

$$y = (m \cdot x - x_1)(x - x_2)$$

b = \_\_\_\_\_

c = \_\_\_\_\_

Modify the values for b and c in the code if necessary.

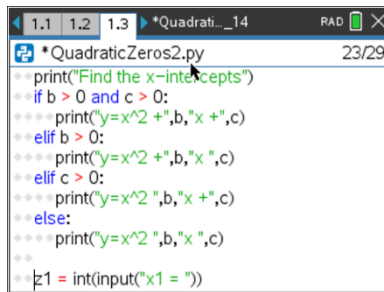

5. Does your code match the code to the right?

```

1.1 1.2 1.3 *Quadrati..._14 RAD 13/29
*QuadraticZeros2.py
from math import *
from random import *
#-----
for c in range(5):
    x1 = randint(-10,10)
    x2 = randint(-10,10)
    m = randint(2,7)
    b = (-x1) + (-x2*m)
    c = x1 * x2
    print("Find the x-intercepts")
    
```

6. When distributing m in step 4, your final equation started with  $mx^2$  instead of  $x^2$ .  
How can you modify the print statements to show  $mx^2$  instead of  $x^2$ ?  
Be careful. You want the value of m to display not the letter m.

```

1.1 1.2 1.3 *Quadrati..._14 RAD 23/29
*QuadraticZeros2.py
print("Find the x-intercepts")
if b > 0 and c > 0:
    print("y=x^2 +",b,"x +",c)
elif b > 0:
    print("y=x^2 +",b,"x ",c)
elif c > 0:
    print("y=x^2 ",b,"x +",c)
else:
    print("y=x^2 ",b,"x ",c)
z1 = int(input("x1 = "))
    
```

Original

Modified

7. How does the user input change?

Let's look at a sample problem:

$$4x^2 + 25x - 21 = 0$$

$$(4x - 3)(x + 7) = 0$$

$$4x - 3 = 0 \quad x + 7 = 0$$

$$x = 3/4 \quad x = -7$$

Not all of the answers will be fractions, but some will be fractions.

The original code:

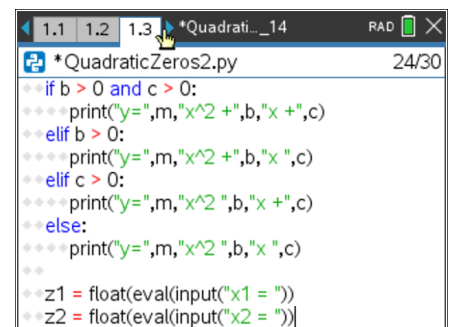

```
z1 = float(input("x1 = "))
```

will not allow the user to enter the division sign.

To perform a calculation then store as a float, use the eval() function.

Modify the two input lines to:

```
z1 = float(eval(input("x1 = "))
z2 = float(eval(input("x2 = "))
```

```

1.1 1.2 1.3 *Quadrati..._14 RAD 24/30
*QuadraticZeros2.py
if b > 0 and c > 0:
    print("y=",m,"x^2 +",b,"x +",c)
elif b > 0:
    print("y=",m,"x^2 +",b,"x ",c)
elif c > 0:
    print("y=",m,"x^2 ",b,"x +",c)
else:
    print("y=",m,"x^2 ",b,"x ",c)
z1 = float(eval(input("x1 = "))
z2 = float(eval(input("x2 = "))
    
```

8. You have one more modification to make. The original project had the line:

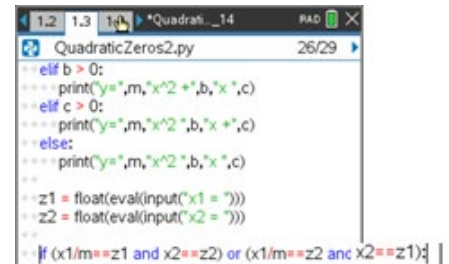

```
if (x1 == z1 and x2== z2) or (x1 == z2 and z1== x2):
```

Modify the if statement so it include the new coefficient m.

*Execute your program. Verify your if statement works.*

9. Did you change the code to:

```
if (x1/m==z1 and x2==z2) or (x1/m==z2 and x2==z1):
```

```

1.2 1.3 1.4 *Quadrati..._14 RAD
QuadraticZeros2.py 26/29
elif b > 0:
    print("y=",m,"x^2 +",b,"x ",c)
elif c > 0:
    print("y=",m,"x^2 ",b,"x +",c)
else:
    print("y=",m,"x^2 ",b,"x ",c)
z1 = float(eval(input("x1 = ")))
z2 = float(eval(input("x2 = ")))
if (x1/m==z1 and x2==z2) or (x1/m==z2 and x2==z1):

```

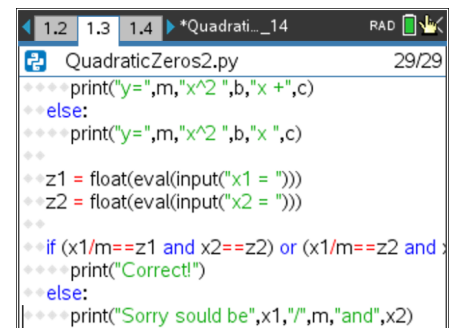

10. Lastly, modify your print statement if the user input is incorrect.

Original:

```
print("Sorry sould be",x1,"and",x2)
```

Change To:

```
print("Sorry sould be",x1,"/",m,"and",x2)
```

```

1.2 1.3 1.4 *Quadrati..._14 RAD
QuadraticZeros2.py 29/29
print("y=",m,"x^2 ",b,"x +",c)
else:
    print("y=",m,"x^2 ",b,"x ",c)
z1 = float(eval(input("x1 = ")))
z2 = float(eval(input("x2 = ")))
if (x1/m==z1 and x2==z2) or (x1/m==z2 and x2==z1):
    print("Correct!")
else:
    print("Sorry sould be",x1,"/",m,"and",x2)

```

**Challenge:**

Create a **QuadraticZero3** program that generates equations with two fractional x-intercepts.

For example,  $6x^2 - 11x - 35 = 0$  factors to  $(3x + 5)(2x - 7) = 0$ .

The x-intercepts would be  $x = -5/3$  and  $x = 7/2$ .
